#### Regulatory sequence analysis

# Sequence models

(Bernoulli and Markov models)

Jacques.van.Helden@ulb.ac.be

Université Libre de Bruxelles, Belgique Laboratoire de Bioinformatique des Génomes et des Réseaux (BiGRe) http://www.bigre.ulb.ac.be/

### Why do we need random models?

- Any pattern discovery relies on an underlying model to estimate the random expectation.
  - This model can be simple (succession of independent and equiprobable nucleotides) or more elaborate (differences in oligonucleotide composition).
  - The choice of an inappropriate model can lead to false conclusions.
  - In practice, a sequence model can be used to generate random sequences, which will serve to validate some theoretical assumptions.
- Example: comparison of observed and expected occurrences with the binomial distribution, as applied with oligo-analysis:
  - Relies on an assumption that successive oligonucleotides are independent from each other.
  - This is clearly not the case: each k-letter word depends on the k-1 neighbour words on both sides. How far does it affect the conclusions?
  - We could test it by generating random sequences, counting words, and fitting the distribution of observed occurrences with a binomial distribution.

### Probability of a sequence segment

- What is the probability for a given sequence segment (oligonucleotide, "word") to be found at a given position of a DNA sequence?
- Different models can be chosen

#### Bernoulli model

- Assumes independence between successive nucleotides.
- The probability of each residue is fixed a priori (prior residue probability)
  - **Example**: P(A) = 0.35; P(T) = 0.32; P(C) = 0.17; P(G) = 0.16
- Particular case: equiprobable residues
  - P(A) = P(T) = P(C) = P(G) = 0.25
  - Simple, but NOT realistic!

#### Markov model

- The probability of each residue depends on the m preceding residues.
- The parameter m is called the order of the Markov model
- Remark: a Markov model of order 0 is a Bernoulli model.

#### Independent and equiprobable nucleotides

 The simplest model: Bernoulli with identically and independently (i.i.d.) distributed nucleotides.

$$p = P(A) = P(C) = P(G) = P(T) = 0.25$$

- The probability of a sequence
  - Is the product of its residue probabilities (independence)
  - Equiprobability: since all residues have the same probability, it is simply computed as the residue proba (p) to the power of the sequence length (L)
    - S is a sequence segment (e.g. an oligonucleotide)
    - L length of the sequence segment
    - p nucleotide probability
    - *P(S)* is the probability to observe this sequence segment at given position of a larger sequence
- Example
  - $P(CACGTG) = 0.25^6 = 2.44e^{-4}$

$$P(S) = p^L$$

#### Bernoulli model: independently distributed nucleotides

- A more refined model consists in using residue-specific probabilities. The probability of each residue is assumed to be constant on the whole sequence (Bernoulli schema).
- The probability of a sequence is the product of its residue probabilities.
  - i=1..k is the index of nucleotide positions is the residue found at position I  $P(r_i)$  is the probability of this residue
- Example: non-coding sequences in the yeast genome
  - P(A) = P(T) = 0.325
     P(C) = P(G) = 0.175
     P(CACGTG) = P(C) P(A) P(C) P(G) P(T) P(G) = 0.325<sup>4</sup> \* 0.175<sup>2</sup> = 9.91E<sup>-5</sup>

$$P(S) = \prod_{i=1}^{L} P(r_i)$$

#### Markov chains and transition matrices

$$P(r_i \mid S_{i-m,i-1})$$

#### **Transition matrix, order 1**

TT	P(A TT)	P(C TT)	P(G TT)	P(T TT)

- In a Markov model, the probability to find a letter at position i depends on the residues found at the m preceding residues.
- The tables represent the transition matrices for Markov chain models of order m=1 (top) and m=2 (bottom).
- Each row specifies one *prefix*, each column one suffix.
- The values indicate the probability to observe a given residue (suffix  $r_i$ ) at position (i) of the sequence, as a function of the m preceding residues (the prefix  $S_{i-m,i-1}$ )
- Particular case
  - A Bernoulli model is a Markov model of order 0.

### Markov model estimation ("training")

 Transition frequencies for a Markov model of order m can be estimated from the frequencies observed for oligomers (k-mers) of length k=m+1 in a reference sequence set.

#### Example

- □ The upper table shows dinucleotide frequencies (k=2) computed from the whole set of upstream sequences of the yeast Saccharomyces cerevisiae.
- This table can be used to estimate a Markov model of order m = k-1 = 1.

Dinucleotide frequencies				
Sequences	Occurrences	Frequency		
S	N(S)	F(S)		
AA	526,149	0.112		
AC	251,377	0.054		
AG	275,056	0.059

### Examples of transition matrices

- The two tables below show the transition matrices for a Markov model of order 1 (top) and 2 (bottom), respectively.
- Trained with the whole set of non-coding upstream sequences of the yeast Saccharomyces cerevisiae.
- Notice the high probability of transitions from AA to A and TT to T.

### Markov chains and Bernoulli models

- By extension of the concept of Markov chain, Bernoulli models can be qualified as Markov models of order 0 (the order 0 means that there is no dependency between a residue and the preceding ones).
- The prior probabilities of a Makov model of order m=0 can be estimated from the residue of single nucleotides (k=m+1=1) in a background sequence set.
- The table below shows the residue frequencies in the genomes of the yeast Saccharomyces cerevisiae and the bacteria Escherichia coli K12, respectively.
- Notice the strong differences between these genomes.

#### Markov order 0 = Bernouli

Α	С	G	T Genome
0.310	0.191	0.191	0.309 Saccharomyces cerevisiae
0.246	0.254	0.254	0.246 Escherichia coli K12

### Scoring a sequence segment with a Markov model

The example below illustrates the computation of the probability of a sequence segment P(S|B) with a background Markov model B of order 2, calibrated from 3nt frequencies on the yeast genome.

#### **CCTACTATATGCCCAGAATT**

### Background sequences

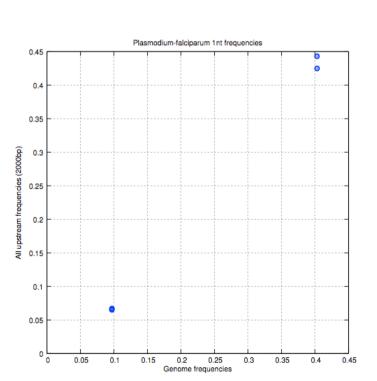

- The frequencies observed for a *k*-letter word in a reference sequence set (background sequence) can be used to estimate the expected frequencies of the same *k*-letter word in the sequences to be analyzed.
- Typical background models:
  - Whole genome
    - But this will bias the estimates towards coding frequencies, especially in microbial organisms, where the majority of the genome is coding.
  - Whole set of intergenic sequences
    - More accurate than whole-genome estimates, but still biased because intergenic sequences include both upstream and downstream sequences
  - Whole set of upstream sequences, same sizes as the sequences to be analyzed
    - Requires a calibration for each sequence size
  - Whole set of upstream sequences, fixed size (default on the web site)
    - Reasonably good estimate for microbes, NOT for higher organisms.

### Nucleotide composition of the Plasmodium upstream sequences

- The genome shows a strong richness in A and T residues (80%AT).
- This enrichment is even stronger in upstream non-coding sequences (86%AT).

#### **Frequencies**

### Chaos representation - upstream frequencies

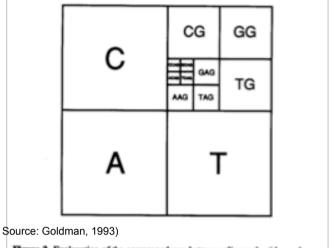

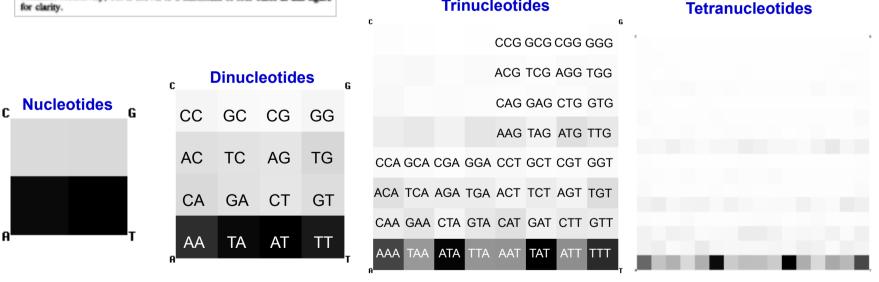

Figure 2. Explanation of the correspondence between oligonucleotides and areas of the CGR of DNA sequences. Each base gives a point in the quadrant labelled with that base; the sub-quadrant is determined by the preceding base, the subsub-quadrant (e.g. 'TAG') by the base preceding that, etc. This correspondence continues recursively, but is shown to a maximum of four bases in this figure for clarity.

- The chaos representation (Jeffrey, 1990) permits to visualize oligonucleotide frequencies and detect enrichment in particular ones.
- Plasmodium upstreal sequences are particularly rich for the following motifs
  - A, T nucleotides

**Trinucleotides** 

- Oligonucleotides made of As and Ts only (last rw pf each chaos map)
- Poly-A and poly-T oligos (bottom corners of the maps)
- (TA){n} motifs (the darkest boxesfrom dinucleotides to tetranucleotides.

Goldman. Nucleotide, dinucleotide and trinucleotide frequencies explain patterns observed in chaos game representations of DNA sequences. Nucleic Acids Res (1993) vol. 21 (10) pp. 2487-91 Jeffrey. Chaos game representation of gene structure. Nucleic Acids Res (1990) vol. 18 (8) pp. 2163-70

#### Hexanucleotide frequencies in Plasmodium Genome versus upstream (2Kb)

 Hexanucleotides show a very wide range of frequencies in the whole genome (X axis) as well as in the subset of upstream sequences (max 2kb, Y axis).
